

PARALLEL IMPLEMENTATION OF FRINGE SEARCH

Lukas Mosimann, Christian Zeman

ETH Zürich
Zürich, Switzerland

ABSTRACT

Describe in concise words what you do, why you do it (not necessarily in this order), and the main result. The abstract has to be self-contained and readable for a person in the general area. You should write the abstract last.

1. INTRODUCTION

This project was part of the course *Design of Parallel and High-Performance Computing* given by Torsten Hoefler and Markus Püschel in autumn 2013 at ETH Zürich.

Motivation. Pathfinding is an important part in many applications, especially in computer games and robotics. Fringe search is a popular algorithm for single-pair shortest path problems. Unlike A* it won't guarantee to find the shortest path, but rather a path "short enough". The advantage of Fringe Search is that it generally outperforms A* as shown in [1].

In [2] a parallel implementation of Fringe Search has been done for a distributed memory environment. The goal of this paper was the implementation and benchmarking of a parallel version of Fringe Search for a shared memory environment.

Related work. This paper is mainly based on three papers. The Fringe Search algorithm was introduced in [1]. S. Brand and R. Bidarra implemented a parallel version in a distributed memory environment described in [3] and a bit more specific in the Master Thesis of S. Brand [2]. In this paper the implementation was done for a shared memory environment.

2. BACKGROUND: SHORTEST PATH PROBLEM

In this section we formally define the single-pair shortest path problem and we consider and introduce two algorithms that are used to solve it.

Single-pair shortest path problem. A problem where the goal is to find the shortest path between a start and an end node in a directed or undirected graph. In our case we used a directed graph.

A*. A very popular algorithm that uses a best-first search approach for solving the single-pair shortest path problem.

For the best-first search it uses a heuristic function (e.g. Euclidean distance or Manhattan distance to end node). It always finds the shortest possible path and therefore it's called optimal. It uses a priority queue for the nodes and therefore each insert into the queue has complexity $O(\log n)$.

Fringe Search. A single-pair shortest path algorithm that is similar to A*, but instead of a priority queue that always has the most promising node first, it stores the nodes in a linked list where an insert has the complexity $O(1)$ and visits a node if it's "promising enough" which is determined by a global threshold value that will be continuously increased. It's not optimal (it doesn't guarantee to find the shortest path) but it is generally faster than A*, as shown in [1]. An example of the algorithm can be found in figure 1.

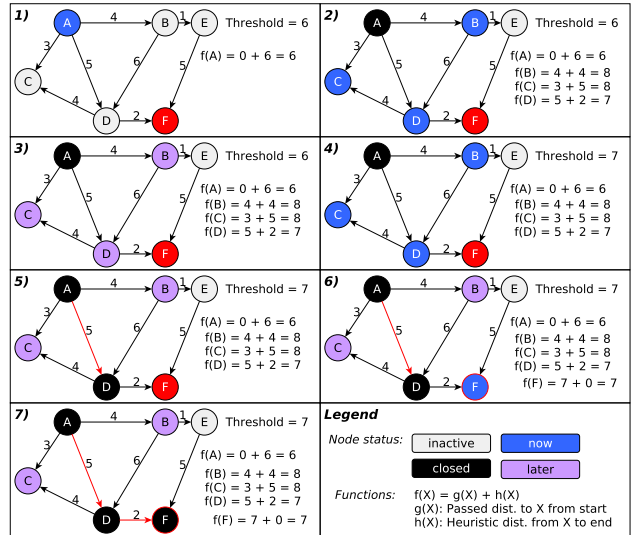

Fig. 1. Fringe Search example

3. CONCEPT AND IMPLEMENTATION

In this section we will show how the implementation has been done and illustrate the used locking concepts.

Graph structure. We used a directed graph implemented as adjacency list. This means that each node has a list of

pointers to the edges that connect it to other nodes.

Linked lists. We used two doubly linked lists we will henceforth call the "nowlist" and the "laterlist". The nowlist generally contains the nodes that have status *now* whereas the laterlist contains the nodes that have status *later*. Whenever the nowlist is empty we increase the threshold and swap the two lists as we also swap the definition of the status (*now* will become *later* and vice versa).

Sequential Fringe Search. As a first step we implemented a strictly sequential Fringe Search in order to have a basis for the parallel implementation and also as a reference for the benchmarks regarding the speedup of the parallel version.

Parallel Fringe Search. Besides the necessary locks for the insertion and removal from the lists the threshold relaxation part is the bottleneck because this part has to be done sequentially by only one thread. The pseudocode can be found in algorithm 1.

Locks: Avoiding deadlocks. In order to avoid deadlocks we always lock in the same direction (see figure 2). If we don't know whether the second node we would like to lock is in the correct direction (e.g. left in the nowlist) we must not force a lock. This can only occur if we want to move a node in the nowlist and this is only the case if we've found a shorter path to a node that already has a path that is below threshold. In this case we can try locking it. If the try is successful we can update the path and move it and if not we just leave the old path that was already below threshold. This does not change the behaviour of the algorithm since the node was below threshold anyway (actually this node easily could have been closed by another thread before we'd found the better path), but acting like this we ensure that no deadlocks can happen.

Fig. 2. Locking direction

Locks: Insert nodes. The sequence for inserting nodes is shown in figure 3.

Locks: Remove nodes. The sequence for removing nodes is shown in figure 4.

Now comes the "beef" of the report, where you explain what you did. Again, organize it in paragraphs with titles. As in every section you start with a very brief overview of

Fig. 3. Insert node into list

the section.

In this section, structure is very important so one can follow the technical content.

Mention and cite any external resources that you used including libraries or other code.

4. EXPERIMENTAL RESULTS

Here you evaluate your work using experiments. You start again with a very short summary of the section. The typical structure follows.

Experimental setup. Specify the platform (processor, frequency, maybe OS, maybe cache sizes) as well as the compiler, version, and flags used. If your work is about performance, I strongly recommend that you play with optimization flags and consider also icc for additional potential speedup.

Then explain what kind of benchmarks you ran. The idea is to give enough information so the experiments are reproducible by somebody else on his or her code. For sorting you would talk about the input sizes. For a tool that performs NUMA optimization, you would specify the programs you ran.

Results. Next divide the experiments into classes, one paragraph for each. In each class of experiments you typically pursue one questions that then is answered by a suitable plot or plots. For example, first you may want to investigate the performance behaviour with changing input size, then how your code compares to external benchmarks.

For some tips on benchmarking including how to create a decent viewgraph see pages 22–27 in [4].

Comments:

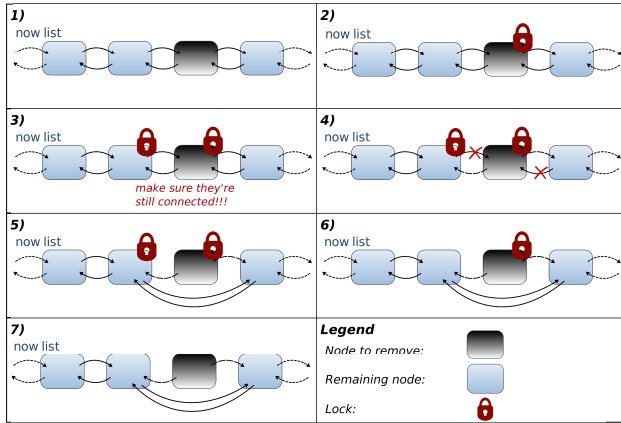

Fig. 4. Remove node from list. Note: The pointers of the removed node remain so that a traversing thread won't get lost.

- Create very readable, attractive plots (do 1 column, not 2 column plots for this report) with readable font size. However, the font size should also not be too large; typically it is smaller than the text font size. An example is in Fig. ?? (of course you can have a different style).
- Every plot answers a question. You state this question and extract the answer from the plot in its discussion.
- Every plot should be referenced and discussed.

5. CONCLUSIONS

Here you need to summarize what you did and why this is important. *Do not take the abstract* and put it in the past tense. Remember, now the reader has (hopefully) read the report, so it is a very different situation from the abstract. Try to highlight important results and say the things you really want to get across such as high-level statements (e.g., we believe that is the right approach to Even though we only considered x, the technique should be applicable) You can also formulate next steps if you want. Be brief. After the conclusions there are only the references.

6. FURTHER COMMENTS

Here we provide some further tips.

Further general guidelines.

- For short papers, to save space, I use paragraph titles instead of subsections, as shown in the introduction.
- It is generally a good idea to break sections into such smaller units for readability and since it helps you to (visually) structure the story.

- The above section titles should be adapted to more precisely reflect what you do.
- Each section should be started with a very short summary of what the reader can expect in this section. Nothing more awkward as when the story starts and one does not know what the direction is or the goal.
- Make sure you define every acronym you use, no matter how convinced you are the reader knows it.
- Always spell-check before you submit (to us in this case).
- Be picky. When writing a paper you should always strive for very high quality. Many people may read it and the quality makes a big difference. In this class, the quality is part of the grade.
- Books helping you to write better: [5] and [6].
- Conversion to pdf (latex users only):

```
dvips -o conference.ps -t letter -Ppdf -G0 conference.dvi
```

and then

```
ps2pdf conference.ps
```

Graphics. For plots that are not images *never* generate the bitmap formats jpeg, gif, bmp, tif. Use eps, which means encapsulate postscript. It is scalable since it is a vector graphic description of your graph. E.g., from Matlab, you can export to eps.

The format pdf is also fine for plots (you need pdflatex then), but only if the plot was never before in the format jpeg, gif, bmp, tif.
